IMMUNOSPECIFICALLY BIND TO
B LYMPHOCYTE STIMULATOR PROTEIN
(as amended)

DECLARATION OF RODGER SMITH UNDER 37 C.F.R. § 1.132

Commissioner for Patents
Alexandria, VA 22313-1450

Sir:

I, Rodger Smith Ph.D., hereby declare and state as follows:

1. I am currently employed as a Senior Scientist I in the Lead Product Development group at Human Genome Sciences, Inc. (HGS), which I understand to be the assignee of the above-captioned patent application. I earned my Ph.D. in 1989 from the Department of Microbiology at the University of Illinois, Urbana -Champaign, Illinois. It was during my thesis research that I first began work on cloning and sequencing of antibody genes. From 1990 to 1999, I worked as a Scientist in the Molecular Biology and Assay Development groups at IGEN International, Inc. (now known as Bioveris Corp.) where my primary responsibilities were developing and characterizing antibody reagents for therapeutic and diagnostic applications. A portion of this work entailed the design and construction of both human and mouse V-domain antibody repertoire libraries for display on the surface of bacteriophage including in 1997 an SBIR grant sponsored by The Department of the Army to construct and validate a large semi-synthetic human phage antibody display library. In 2000, I joined the Antibody Development group (now known as the Lead Product Development group) at Human Genome Sciences where I have

continued to work with phage antibody display technology, primarily for developing therapeutic antibodies to a variety of novel protein targets. A large portion of this work involved screening and characterizing hundreds of antibody leads at both the DNA sequence and protein level. I am the co-author of 12 scientific articles and several issued and pending patent applications. A copy of my curriculum vitae is attached as Exhibit A.

2. I have been shown and have examined U.S. Patent Application No. 09/880,748 (the '748 Application), captioned above, which I understand was filed on June 15, 2001. I will refer to the '748 Application as "the Application."

3. I have been shown and have examined Table 1 and the Sequence Listing of U.S. Patent Application No. U.S. Patent Application No. 60/212,210 (the '210 Application), which I understand was filed on June 16, 2000. It is my understanding that Table 1 and SEQ ID NOS 1-2128 of the Sequence Listing of the '748 and the '210 applications are identical.

4. I have been asked by patent counsel for Human Genome Sciences to explain how an antibody scientist familiar with the sequences of antibodies would be able to accurately recognize the beginning of an immunoglobulin light chain variable domain (VL domain) in the amino acid sequence of an scFv protein. Moreover, I have been asked if and how an antibody scientist, based on the information presented in Table 1 of the '748 application and the sequences shown in SEQ ID NOS:1-2128 would have been able to identify and correct any errors in the delineation of the VL domain in column 3 of Table 1.

BACKGROUND

5. Intact immunoglobulin (i.e., antibody) molecules are composed of heavy chain polypeptides and light chain polypeptides that are joined together by disulfide bonds. Each heavy and light chain can be further subdivided into a Variable (V) and a Constant (C) region. The variable regions of the heavy and light chains of a given antibody make up the antigen binding-portion an antibody. The variable regions of heavy chains are known as VH domains and the variable regions of light chains are known as VL domains. The constant region of an immunoglobulin heavy chain determines the effector functions of an antibody (e.g. the ability to activate complement or the ability to cross the placenta).

The constant regions of light chains serve more of a structural role, allowing the light chain to associate with the heavy chain by disulfide bonding. Constant regions are further subdivided into particular isotypes, based on the sequences of these regions. There are five classes of heavy chain isotypes known as IgA, IgG, IgM, IgD, and IgE and two classes of light chain isotypes known as kappa and lambda.

6. For the purposes of this Declaration it is necessary to understand that there are distinct sets of immunoglobulin variable regions that are found in association with kappa constant regions and lambda constant regions, respectively. These two sets of variable regions are encoded by two different loci in the human genome. The variable regions that associate with kappa constant regions are referred to as $V\kappa$ (for Variable kappa) while the variable regions that associate with lambda constant regions are referred to as $V\lambda$ (for Variable lambda).

7. It is also useful to understand that the sequences of the variable regions of both heavy and light chain genes encoded by the genome are referred to as “germline” sequences. The sequences encoding the variable regions of an antibody may be mutated in the course of the life of an antibody-producing B cell through a process called somatic hypermutation. The variable regions of an antibody obtained from a B cell that has undergone somatic hypermutation will have sequences that deviate from the precise sequence of the germline sequence.

8. An scFv is a single chain antibody that is (usually) produced using phage display technology in which the amino acid sequence of an immunoglobulin heavy chain variable domain (VH domain) is linked to the amino acid sequence of an immunoglobulin light chain variable domain (VL domain) by a synthetic linker sequence. The resulting scFv protein is conformationally similar to the antigen binding region of an intact antibody. ScFvs may contain VH and VL regions that have germline or non-germline sequences.

DEFINING THE SEQUENCE OF THE VL REGION IN AN SCFV

9. The beginning of the VL region in an scFv may be easily delineated by 1) determining whether the scFv contains a kappa or a lambda variable domain and then 2)

calculating the first amino acid sequence based on a standard numbering system for immunoglobulin variable regions that was established by Elvin A. Kabat and Tai Te Wu in the 1970's that is widely used by immunologists even today. This is explained in more detail below.

Determining if the VL in the scFv is a V κ or a V λ

10. It is clear from the specification of the '748 Application that the scFvs described in Table 1 and shown in the sequence listing contain human VH and VL regions. Paragraph [0298] indicates the scFvs are "human scFvs" and that each scFv sequence in the Sequence Listing is annotated as being from "Homo sapiens." It is also clear from the specification of the '748 Application that the scFvs described in Table 1 and shown in the sequence listing contain a linker region that contains a core sequence of 15 amino acid residues consisting of Gly Gly Gly Gly Ser Gly Gly Gly Gly Ser Gly Gly Gly Gly Ser (or (Gly₄Ser)₃). As an example, take the scFv of SEQ ID NO:1 which is described in Table 1 at page 287 to comprise the amino acid sequence of a VH domain consisting of amino acids 1 - 122 of SEQ ID NO:1 and an amino acid sequence of a VL domain consisting of amino acids 138 - 248 of SEQ ID NO:1. Therefore, the linker sequence in-between (i.e., of amino acids 123-137 of SEQ ID NO:1) consists of the sequence (Gly₄Ser)₃. Inspection of each of the scFvs reveals that the linker sequence of amino acids between the end of the VH and the start of the VL as defined in Table 1 contains the (Gly₄Ser)₃ sequence.

11. Before June 16, 2000 the sequences of most, if not all human V κ and V λ were known. Attached hereto as Exhibits B-D are printouts from a database of immunoglobulin genes called IgBLAST maintained by the National Center for Biotechnology (NCBI). This database may be accessed on the world wide web at <http://www.ncbi.nlm.nih.gov/igblast/showGermline.cgi>. Exhibit B briefly explains the composition of the sequences in the subset of the IgBLAST database that contains the sequences of germline genes. At the bottom of Exhibit B one can see a series of pull down menus that enable a user to see a set of known of sequences (either amino acid or polynucleotide sequences) for germline genes from a given organism for several loci, including V κ and V λ loci.

12. Exhibits C and D, respectively, show the contents of the germline database when a user requests to see the protein sequences of either human $V\kappa$ or human $V\lambda$ germline genes. At the top of page one of both Exhibits C and D it is clear that the sequences on the germline genes were taken from scientific work that was performed and published prior to June 16, 2000.

13. Thus, as described in the '748 application, at paragraph [0669], it would be routine to align the sequences of each the 2128 scFvs disclosed in Table 1, against known human germline VL (both $V\kappa$ and $V\lambda$) sequences to determine if a given scFv contains a kappa or a lambda variable region. This would be accomplished by identifying whether the "closest germline" VL domain is a $V\kappa$ or a $V\lambda$. The results of aligning the scFvs of each of SEQ ID NOS:1-2128 against a database containing the sequences of the 36 human $V\lambda$ and 46 human $V\kappa$ genes identified in NCBI's human IgBLAST database are shown in a table attached hereto as Exhibit E. The first column of the table in Exhibit E indicates the SEQ ID NO of the scFv, the second column indicates the name of germline gene that is most similar to the VL region of the scFv, the third column indicates the isotype (kappa or lambda) of the germline gene shown in column 2 and the fourth column indicates the percent identity between the VL region of the scFv and the closest germline gene.

Kabat-Wu Numbering System

14. Elvin A. Kabat and Tai Te Wu developed a numbering system for consistent amino acid numbering of immunoglobulin variable regions that would result in certain amino acid numbers always being assigned to CDR regions of VH, $V\kappa$ or $V\lambda$ regions. With respect to light chain variable regions, Kabat and Wu, through extensive analysis of many light chain variable regions recognized that there is an invariant cysteine residue at what they define as position 23 of an immunoglobulin light chain variable. This statement is supported by a sentence in the abstract of Johnson and Wu¹ (provided herewith as Exhibit F) which indicates the CDR1 of light chains begins after the first invariant cysteine at position no. 23 in light chains. Moreover, at the top of the right hand column on page 214, Johnson and Wu indicate that the Kabat-Wu numbering scheme is more clearly set forth in the Introduction of the fifth edition of a book Kabat, Wu and

others compiled entitled *Sequences of Proteins of Immunological Interest*², a portion of which is attached hereto as Exhibit G. Table 1 from the Introduction of *Sequences of Proteins of Immunological Interest* explains that the sequence of amino acids prior to the first CDR region light chains is numbered from 1-23 (of which amino acid 23 is the invariant cysteine), but that lambda chains contain a deletion (i.e., have no amino acid corresponding to) what Kabat-Wu number as amino acid position 10 in light chains. In effect, this makes the invariant cysteine residue in lambda light chains occur at the 22nd amino acid residue in lambda light chains. This invariant cysteine at the 22nd amino acid residue of lambda light chains and the 23rd amino acid residue of kappa light chains (both of which are referred to as the invariant cysteine residue at position no. 23 by the Kabat-Wu numbering scheme), can be used to accurately identify the first amino acid residue in the VL region of an scFv light chain, after one has identified whether the VL region is a V κ or V λ as described above.

15. Thus, to identify the first amino acid position of the VL region, one simply must identify the cysteine amino acid residue that is approximately 23 amino acid residues after the (Gly₄Ser)₃ sequence in the linker region. Having identified this cysteine residue, then one assigns it as amino acid residue number 23 or 22, depending on whether the closest identified germline gene is a kappa or lambda variable region, respectively. Finally one must simply count backwards to 1 to identify the first amino acid of the VL region.

16. As a general rule, the first cysteine residue after the (Gly₄Ser)₃ sequence in the linker region will be the cysteine residue that Kabat-Wu defines as the cysteine at amino acid position No. 23. In the 2128 scFv sequences disclosed in Table 1 and the Sequence Listing of the '748 application, there are only 4 cases where the first cysteine residue after the (Gly₄Ser)₃ sequence in the linker region is not the cysteine residue defined by Kabat-Wu numbering as position number 23. The exceptions include:

¹ Johnson, G. and T. T. Wu. (2000) Kabat Database and its application: 30 years after the first variability plot.. Nucleic Acids research 28:214-218

² Kabat E.A., et al. (1991) *Sequences of Proteins of Immunological Interest*. Fifth Edition. NIH Publication No. 91-3242

- ❖ SEQ ID NOS:125, 693 and 1680 in which there is a cysteine residue prior to amino acid no. 23 in addition to the cysteine at amino acid no. 23; and
- ❖ SEQ ID NO:1554 in which the first cysteine residue is not found until amino acid position no. 89. However, if one examines the region where one expects to find the cysteine residue defined by Kabat-Wu numbering as position number 23, there is a tryptophan residue. Tryptophan is encoded by a codon that shares third position wobble with the codons encoding cysteine residues. The absence of a cysteine residue in this case at Kabat-Wu position no. 23, might be explained by a mutation from the germline sequence; or, more likely - the absence of a cysteine residue at Kabat Wu position No. 23 in SEQ ID NO:1554, is best explained by the presence of a sequencing error because the cysteine residue at position no. 23 is important for the tertiary structure of the variable regions. Absence of this cysteine is apt to disrupt the tertiary structure required by the scFv to bind antigen.

17. Column 5 of the Table in Exhibit E shows the number of amino acids after the (Gly₄Ser)₃ sequence prior to amino acid position no. 1 in the VL region and column 6 of the Table in Exhibit E shows the identity of the amino acids after (Gly₄Ser)₃ sequence prior to amino acid position no. 1 in the VL region. In 99% (1301/1308) of cases where there are extra amino acids after the (Gly₄Ser)₃ sequence, the identity of the amino acids is A, AL or AF. These results indicate that these amino acids most likely arose as a "side-effect" of the cloning strategy used to create the scFvs constructs in the initial generation of the scFv library and further confirm that these residues are not part of the VL region of these scFvs of SEQ ID NOS:2128.

18. Additionally, in some cases where the closest germline gene in V2-13, the first amino acid residue of the VL is calculated to be the last serine residue of the (Gly₄Ser)₃ sequence (see, for example, SEQ ID NOS: 4 and 5³ for which Column 5 of

³ The following is a complete list of the 238 SEQ ID NOS cases where the closest germline gene is V2-13 and the first amino acid residue of the VL is calculated to be the last serine residue of the (Gly₄Ser)₃ sequence: 4, 5, 397, 512, 834, 835, 842, 848, 850, 851, 877, 892, 893, 896, 900, 908, 911, 912, 913, 914, Serial No. 09/880,748

Exhibit E shows a -1 value). Note that the first amino acid residue of the germline V2-13 residue in Exhibit D is a Serine. Again, this result indicates that in cloning the scFvs to make the original scFv library, a cloning strategy was used that was able to take advantage of the fact that the last amino acid of the (Gly₄Ser)₃ sequence could also serve as the first amino acid residue of the VL region⁴.

SUMMARY

19. On or before June 16, 2000, an antibody scientist examining the information presented in Table 1 and the sequences of SEQ ID NOS:1-2128 of the Sequence Listing of the '748 patent would have readily recognized that in several instances, the amino acid residues defined in Table 1 as making up the VL region of certain scFvs were incorrect for either containing a few additional amino acids 5' of the VL region or for lacking an amino acid at the 5' end of the VL-region. Moreover, an antibody scientist would have had no difficulty in identifying the correct amino acid residue that corresponded to the first amino acid residue of the VL region.

20. I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under § 1001 of

916, 920, 924, 927, 928, 937, 938, 943, 946, 948, 949, 950, 952, 953, 957, 959, 963, 965, 967, 970, 974, 980, 982, 984, 987, 993, 996, 997, 999, 1050, 1054, 1056, 1065, 1102, 1105, 1108, 1109, 1110, 1111, 1112, 1113, 1115, 1116, 1117, 1118, 1119, 1120, 1170, 1178, 1179, 1181, 1182, 1189, 1192, 1198, 1290, 1293, 1294, 1299, 1300, 1303, 1305, 1306, 1307, 1308, 1315, 1316, 1322, 1323, 1328, 1330, 1331, 1335, 1341, 1344, 1346, 1357, 1367, 1370, 1384, 1386, 1387, 1388, 1391, 1393, 1394, 1402, 1416, 1417, 1424, 1425, 1426, 1433, 1438, 1444, 1445, 1470, 1472, 1474, 1588, 1594, 1596, 1609, 1615, 1620, 1621, 1622, 1623, 1624, 1628, 1638, 1639, 1641, 1643, 1646, 1647, 1648, 1651, 1652, 1655, 1657, 1660, 1662, 1665, 1667, 1668, 1670, 1675, 1676, 1678, 1679, 1681, 1692, 1694, 1702, 1703, 1705, 1708, 1718, 1721, 1722, 1723, 1724, 1725, 1726, 1727, 1728, 1729, 1730, 1731, 1732, 1734, 1740, 1741, 1742, 1755, 1761, 1762, 1764, 1765, 1777, 1781, 1785, 1786, 1788, 1790, 1816, 1817, 1818, 1823, 1826, 1871, 1873, 1877, 1907, 1911, 1912, 1914, 1919, 1924, 1929, 1931, 1937, 1938, 1939, 1940, 1941, 1942, 1944, 1947, 2006, 2008, 2010, 2013, 2014, 2015, 2018, 2021, 2022, 2023, 2031, 2032, 2033, 2035, 2036, 2038, 2039, 2046, 2056, 2057, 2058, 2060, 2066, 2067, 2068, 2106, 2107, 2112,

⁴ It is also noted that SEQ ID NO:1389 is another sequence in which, the first amino acid residue of the VL is calculated to be the last serine residue of the (Gly₄Ser)₃ sequence. SEQ ID NO:1389 is most closely related to germline V1-13 which begins with a Q amino acid residue. It is likely that the sequence of this VL region was mutated either prior to being cloned into an scFv construct or during passaging or selection of the scFv library.

Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application captioned above or any patent issuing thereupon.

RESEARCH SCIENTIST

QUALIFICATIONS

- Ph.D. in Molecular Biology with 14 years of industrial laboratory experience.
 - Senior scientist with expertise in phage antibody display technology, therapeutic antibody generation and characterization, in vitro assay development, protein purification and gene cloning and expression.
 - Laboratory and project management experience.
-

PROFESSIONAL EXPERIENCE

Human Genome Sciences, Inc., Rockville, MD

Senior Scientist I, Antibody Development

08/2002-present

- Lead scientist for project involved in the discovery and development of therapeutic antibodies to protective antigens from anthrax and plague causing organisms.
- Developed cloning protocols and selection techniques for affinity maturation of scFv's by phage display.
- Generated large panels of specific binding scFv's to a number of soluble and membrane-associated therapeutic target proteins.
- Developed a variety of electrochemiluminescent-based and cell-based assays to identify and characterize lead candidate therapeutic scFv's and/or IgG's.
- Project manager for outside collaboration focused on the discovery of therapeutic antibodies to 7TM chemokine receptors using human Fab phage display libraries.

Scientist, Antibody Development

04/2000-07/2002

- Developed expression constructs and purification methods for producing homotrimeric and heterotrimeric forms of BlyS and APRIL.
- Developed novel electrochemiluminescent-based assays to evaluate specificity and affinity of antibodies to a G protein-coupled receptor.
- Engineered mammalian antibody expression vectors to streamline cloning of V-domains and enhance expression of IgG.
- Developed methods for epitope mapping of recombinant antibodies using peptide phage display technology.
- Generated assay reagents and developed assay protocols for evaluating immunogenicity and pK of therapeutic antibodies.

- Generated a panel of fully human IgG's that blocked the catalytic activity of a novel angiotensin converting enzyme.

Bioveris Corp. (formerly IGEN International, Inc.), Gaithersburg, MD

Scientist 3, Assay Development

01/1999 – 04/2000

- Manager for laboratory focused on the production, purification and validation of antibody and protein reagents used in diagnostic assay development.
- Developed and produced diagnostic and therapeutic antibody reagents on a contract basis using a large human repertoire phage antibody display library.
- Engineered a phage antibody display vector for production of novel binding reagents such as bivalent single-chain antibodies.

Scientist 1 and 2, Molecular Biology / Molecular Engineering

1990 to 1998

- Principal Investigator (Phase I SBIR) for project focused on constructing a large human repertoire phage antibody display library. Responsibilities included project management, bench research and report writing.
- Optimized primer design, PCR conditions and cDNA cloning methods for generating large human and murine antibody repertoire phage display libraries.
- Coordinated research collaboration involving application of phage antibody display to isolate human and mouse single-chain antibodies with catalytic activity.
- Developed humanized single-chain and bivalent single-chain antibodies for tumor targeting and prodrug activation.
- Developed a bacterial cloning and expression system for high-level production of single-chain antibodies.
- Performed site-directed mutagenesis of an antibody enzyme (abzyme) to delineate catalytic residues.

SUMMARY OF LABORATORY EXPERTISE

Recombinant DNA methods:

mRNA isolation, RT-PCR, 5' RACE, cDNA cloning, vector construction, phage display library construction, site-directed mutagenesis, Northern and Southern hybridization, DNA sequencing, gene transfection, DNA replication assays, DNA diagnostic assays

Protein methods:

Protein Purification (FPLC and BioCad instrumentation), BIAcore analysis, antibody affinity measurements, immunoassay development, SDS-PAGE and Western blotting

Other skills:

Phage display technology, hybridoma production and screening, cell transfection and tissue culture, large scale bacterial fermentation and protein production

EDUCATION

1989 - Ph.D. in Microbiology (Molecular Biology), University of Illinois at Urbana-Champaign. Thesis research in the laboratory of Dr. Edward Voss studying the molecular basis of autoimmunity and anti-DNA autoantibodies in a murine model.

1984 - M.S. in Microbiology, University of Illinois at Urbana-Champaign. Thesis research in the laboratory of Dr. John Scott studying yeast DNA replication enzymes associated with the chromatin of a freely replicating yeast DNA plasmid.

1981- B.S. in Microbiology, Pennsylvania State University, University Park. Cooperative Study for one year in the Microbiology Research Department at Hershey Foods, Inc., Hershey, PA.

GRANTS AND AWARDS

Phase I Small Business Innovation Research (SBIR) grant (\$100,000).
Project Title-Construction of a Large Semi-Synthetic Human Phage
Antibody Display Library, 1997. Granting Agency: Dept. of the Army.

U.S. Public Health Service Traineeship, 1984-1987, University of Illinois, awarded for academic achievement.

Clark Microbiology Award, 1983, 1988 and 1989, University of Illinois, for excellence in teaching.

ISSUED PATENTS

Reaction-Based Selection for Expression of and Concentration of Catalytic Moieties
US Patent Number 6,121,007 Date: Sept. 19, 2000 and 6,177,270B1 Date: Jan. 23, 2001

Cycling DNA/RNA Amplification Electrochemiluminescent Assay
US Patent Number 6,048,687 Date: April 11, 2000

The Isolation and Production of Catalytic Antibodies Using Phage Technology
European Patent Number P09002EPO Date: March 14, 2000

Prodrugs Activated by Targeted Catalytic Proteins
US Patent Number 6,258,360 B1 Date: July 10, 2001

Ig Germline Genes

[What's New?](#)[Introduction](#)[Examples](#)[General Blast
Help](#)[FAQs](#)[Ig Germline
Genes](#)[Retrieve Ig
sequences](#)[Other Resources](#)

Our collections of germline V genes include functional V genes and V genes with Open Reading Frame (ORF) for the heavy chain, the kappa light chain and the lambda light chain from human and mouse. However, no attempt was made to include all polymorphic forms of germline genes (one should instead search the [nr](#) or [Ig sequences](#) database for germline gene polymorphism).

In compiling the germline gene sequences, we have retained the nomenclature by the original authors, but we have excluded the signal peptide sequences and the recombination signal sequences. Amino acid sequences are translated in some cases where only nucleotide sequence records are available in GenBank.

Select the germline genes you want to view:

Organism Locus Sequence type

Although the human Ig kappa locus has not been fully sequenced yet, all of individual genes are likely to have been isolated (Schable KF and Zachau HG, 1993; Brensing-Kuppers J. et al. 1997). The following sequences are taken from these studies.

TABLE I

Amino Acid Residues Associated with Framework (FR) and Complementarity Determining Regions (CDR) of the Variable Domains of Immunoglobulin Light (V_L) and Heavy (V_H) Chains:

Segment	Light Chain	Heavy Chain
FR1	1-23 (with an occasional residue at 0, and a deletion at 10 in V_L chains)	1-30 (with an occasional residue at 0)
CDR1	24-34 (with possible insertions numbered as 27A,B,C,D,E,F)	31-35 (with possible insertions numbered as 35A,B)
FR2 ^a	35-49 ^a	36-49
CDR2	50-56	50-65 (with possible insertions numbered as 52A,B,C) ^b
FR3	57-88	66-94 (with possible insertions numbered as 82A,B,C)
CDR3	89-97 (with possible insertions numbered as 95A,B,C,D,E,F)	95-102 (with possible insertions numbered as 100A,B,C,D,E,F,G,H,I,J,K)
FR4	98-107 (with a possible insertion numbered as 106A)	103-113

^a Five Basilea rabbits (λ) immunized with type II pneumococci and which produced anti-type II pneumococcal polysaccharide had Met at position 48 and an insertion of four amino acid residues between positions 48 and 49; in four of the five the sequence was Glu, Leu, Lys, Ser and the fifth was Trp, Leu, Arg, Lys (53,54,63,64); the others were not sequenced at these positions (for references see table of rabbit λ amino acid sequences.)

^b In the rabbit, Mage et al. (65) consider position 65 in V_H to be in FR3, since it is allotype related.

Kabat Database and its applications: 30 years after the first variability plot

George Johnson and Tai Te Wu*

Departments of Biochemistry, Molecular Biology and Cell Biology, and of Biomedical Engineering, Northwestern University, Evanston, IL 60208, USA

Received July 23, 1999; Revised and Accepted October 13, 1999

ABSTRACT

The Kabat Database was initially started in 1970 to determine the combining site of antibodies based on the available amino acid sequences at that time. Bence Jones proteins, mostly from human, were aligned, using the now-known Kabat numbering system, and a quantitative measure, variability, was calculated for every position. Three peaks, at positions 24–34, 50–56 and 89–97, were identified and proposed to form the complementarity determining regions (CDR) of light chains. Subsequently, antibody heavy chain amino acid sequences were also aligned using a different numbering system, since the locations of their CDRs (31–35B, 50–65 and 95–102) are different from those of the light chains. CDRL1 starts right after the first invariant Cys 23 of light chains, while CDRH1 is eight amino acid residues away from the first invariant Cys 22 of heavy chains. During the past 30 years, the Kabat database has grown to include nucleotide sequences, sequences of T cell receptors for antigens (TCR), major histocompatibility complex (MHC) class I and II molecules and other proteins of immunological interest. It has been used extensively by immunologists to derive useful structural and functional information from the primary sequences of these proteins. An overall view of the Kabat Database and its various applications are summarized here. The Kabat Database is freely available at <http://immuno.bme.nwu.edu>

INTRODUCTION

The purpose of maintaining the Kabat Database of aligned sequences of proteins of immunological interest, in our opinion, is to provide useful correlations between structure and function for this special group of proteins from their nucleotide and amino acid sequences to their tertiary structures (1). These sequences are thus aligned with the ultimate aim of understanding how these proteins are folded and how they can perform their biological functions. We include only coding region sequences that have been published. In some cases, only the amino acid sequences were published, while the corresponding nucleotide sequences were deposited in GenBank. All stored

sequences were then printed out and checked visually against available published sequences. We routinely survey for possible new sequences in journals in our libraries, Medline entries, cross-references from other papers, and author notification; however, we may still miss some sequences. GenBank, on the other hand, contains a substantial number of unpublished sequences. If there are doubts about these sequences or their annotations, please refer to the original papers. The Kabat numbering systems (see the Introduction of 2) for antibody light and heavy chains, for TCR alpha and beta chains, etc., go hand-in-hand with variability calculations. The locations of the CDRs are the theoretically derived positions which can be verified experimentally. Indeed, from the first antigen-antibody Fab complex (3) to the complexes of TCR, processed peptide and MHC class I molecule (4,5), it has been realized that alignment of amino acid sequences and variability calculations can be of utmost importance in understanding how these important macromolecules function biologically. Due to the rapid development of genetic and protein engineering methods, mouse and rat antibodies have been humanized to treat human cancers, viral infections, etc (6). CDRs of selected rodent antibodies are cut out and glued onto human antibody frameworks to minimize rejection by human patients.

Our predicted CDRs are slightly different from Chothia's. A careful comparison can be found from a hyperlink on our website to 'Andrew's Antibody Page' (<http://www.biochem.ucl.ac.uk/~martin/abs/index.html>).

Massive amounts of sequence data are being continuously published in the scientific literature. It is imperative to collect and properly align the sequences so that they can be used by as many researchers in this field as possible. We have previously published five editions of these sequences (see the Introduction of 2). In 1991, the fifth edition (2) consisted of three volumes. Currently, the database is more than five times as large. As of September 29, 1999, the Kabat database contained 1 599 375 and 2 517 756 nt for antibody light and heavy chain variable regions, respectively, as compared to 272 244 and 418 962 nt in 1991. Total numbers of entries, amino acids and bases of other categories of sequences can be obtained by using the 'Current Counts' hyperlink on our website. The collection is available on our website (<http://www.immuno.bme.nwu.edu>) which is free due to the generous support by various research grants from NIH since 1970.

Finally, numerous scientific papers have cited our database, quoting our fourth edition (7), fifth edition (2), or one of our more recent papers (8). On our part, we have been analyzing

the Kabat Database during the past few years with reference to the total numbers of antibody and TCR V-genes, possible evolutionary selection processes, importance of antibody CDRH3s as related to their fine specificities, etc.

KABAT DATABASE

The Kabat Database may be accessed for searching, sequence retrieval and analysis by a few different methods: electronic mail, WWW and ftp. The electronic mail interface has been available since 1993, the WWW interface since 1995 and various formats of the database in electronic format for nearly a decade (8). Our data formats, searching tools, output formats and database structures have gradually been adopted by other immunological databases and interfaces.

Electronic mail interface

An electronic mail interface (seqhnt2@immuno.bme.nwu.edu) provides a non-interactive method for searching and sequence retrieval (9). Sending mail to the server address with the single word 'help' (no quotes) in the message body returns instructions for using the server.

All sequences classes are searchable and returnable. The query format allows making AND/OR/NOT constructed restrictions on the database and amino acid and nucleotide sequence pattern matching with allowable differences. Requests are processed as they are received and depending on the network traffic, take ~1–2 min to be searched and returned to the sender. The returned format is a fixed-line length record of 80 or fewer characters per line for ease in visual inspection and processing by user-written scripts or programs. The characters are plain text.

The query format for the sent request consists of two parts. The first part contains directives for the server to follow while the second part contains specifications of the search. Specification of the extent of data returned, the number of documents to return, starting document and whether plain ASCII text or PostScript should be used in the return format may be entered. Further, one can direct the server to return a distribution, the variability or unaligned raw data for the search specified.

The second part of the query contains the search restrictions on the database. Words separated by AND and OR may be used, as well as searching functions, like nucleotide/amino acid pattern matching and positional restriction matching.

There are basically three steps in translating and performing a search on the Kabat Database: generate the question or query, translate it into a format the server can recognize and decide on the output options desired of the returned matches. For example, if matches of mouse kappa light chains of anti-phosphorylcholine antibodies are desired, the query and restriction on the database would be:

Begin

@mouse and kappa and phosphorylcholine

The '@' before mouse tells the server that matches of the species mouse are desired, rather than searching through the entire database record for instances of the word 'mouse'. More complicated restrictions can be generated using parentheses for grouping and the minus sign '-' for NOT. Finding all rat and rabbit sequences which are not kappa light chains, and returning them as amino acid sequences in PostScript format would be constructed as:

PSAA

Begin

(rat and rabbit) and -kappa

Pattern matching is interpreted as the second part of an AND statement, such that finding all rat and rabbit sequences which are not kappa and contain the nucleotide pattern cagtagctcag with three allowable mismatches, would be sent as:

Begin

(rat and rabbit) and -kappa [implicit AND]

#NM 3

cagtagctcag

More examples of searching and output options may be found in the 'help' file returned from the server.

WWW interface

The WWW interface (8) to the Kabat Database: <http://immuno.bme.nwu.edu> contains searching and analysis tools as well as links to database download sites and other interesting databases. Most of the features found in the electronic mail interface are found in the WWW interface, as well as other tools. The WWW interface is more interactive than the Email and returns results faster, depending on the network traffic.

Searching and analysis tools

SeqhntIII. This grouping of programs allows searches through the annotations and sequence pattern matching of the amino acid and nucleotide sequence data with allowable mismatches. Like the Email server, restrictions on the database may be formulated as AND/OR/NOT constructs. Output extent, output format, maximum documents and starting document may be specified. Browsing of the output results in HTML format allows the user to view the database entries in an easy-to-read format. ASCII text may be selected as output for use in user-generated scripts and programs. PostScript generation allows for printing on a PostScript supporting printer. Sequence matching is returned aligned with the target sequence with nucleotide or amino acid differences from the database sequence displayed in a case change. Since the database contains only coding regions of genes and proteins, the query sequence should be a portion of the coding region being sought.

Variability. Variability and amino acid distributions of sequence groups may be generated for restrictions on the database. The variability plots are in PostScript format and may either be viewed on the screen with an appropriate PostScript viewer (e.g. GNU ghostscript or ghostview) or printed to a postscript-supporting printer. Plots for human and mouse TCR gamma and delta chain variable regions are shown in Figure 1. Scaling of the variability plots may be done allowing comparison of variability plots for different groupings of sequences. Distributions of the amino acids per position may be returned also, including the calculated variability for each position.

Sequence alignment. Alignment of user-entered coding regions of immunoglobulin light chains according to the Kabat numbering system can be performed. Because of the relatively few alignment options available for light chains, most sequences can be aligned. One can start with around 10 amino acid residues or 30 nt. There is no lower limit on the length of sequence to be matched. In some cases though, visual inspection and alignment is necessary, as is for heavy chain alignment,

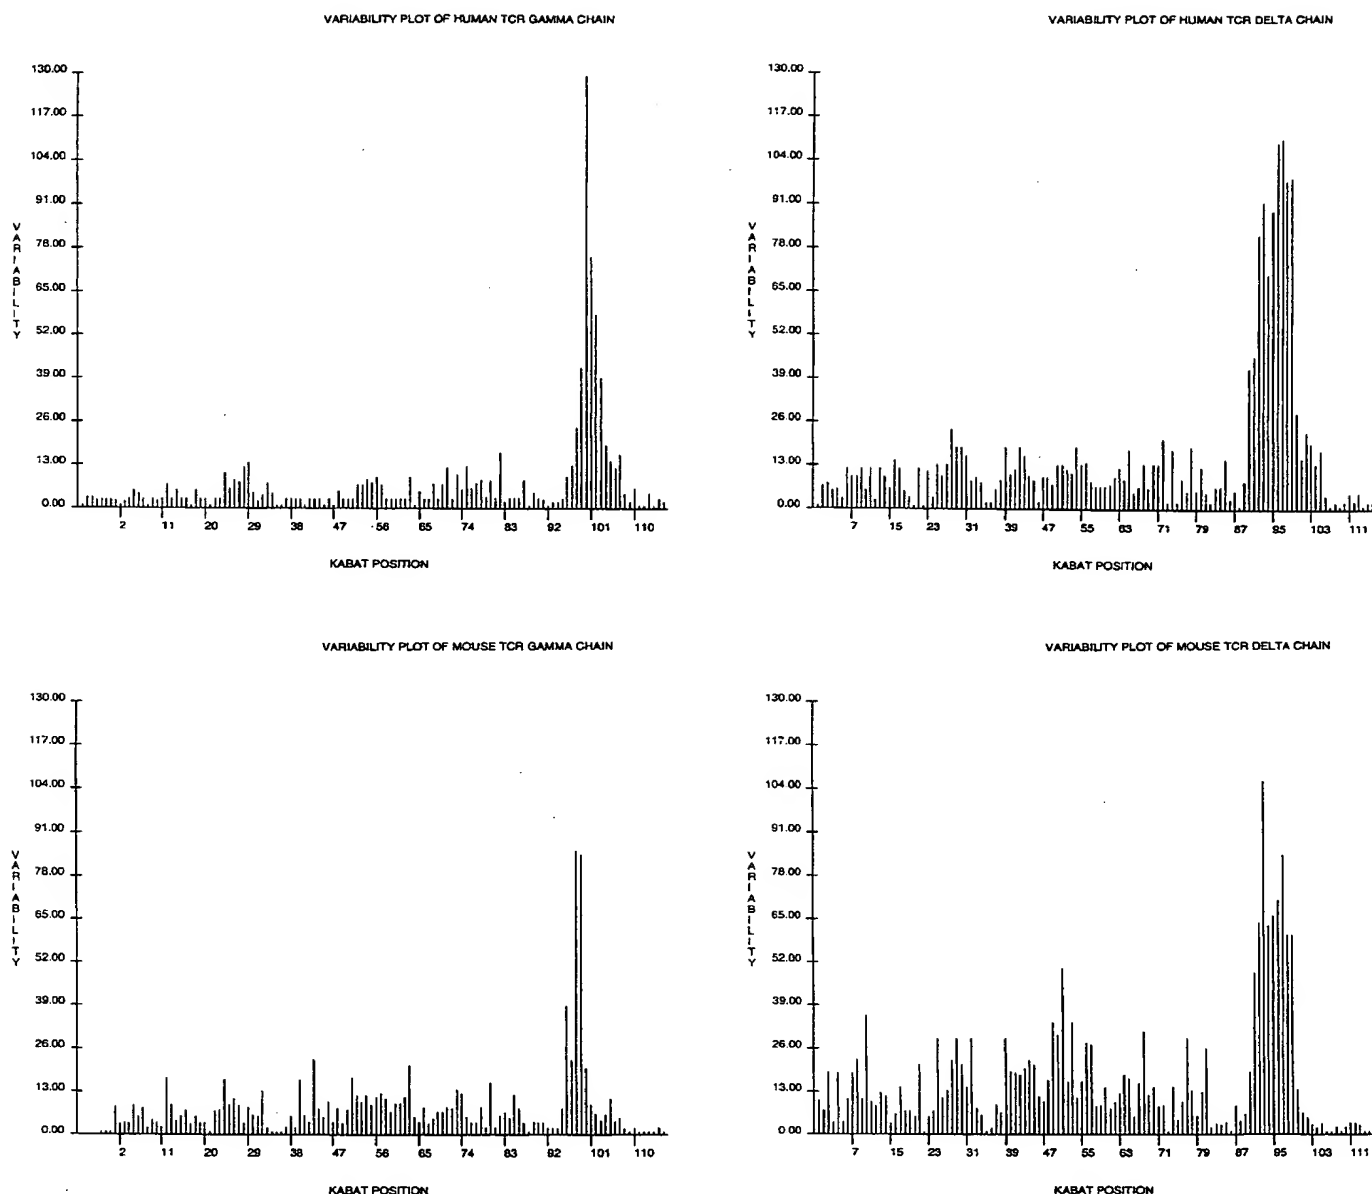

Figure 1. Variability plots for human and mouse TCR gamma and delta chain variable regions, using 377 human gamma, 1260 human delta, 297 mouse gamma and 461 mouse delta partial and complete sequences.

especially within the CDRH3 region, if additional codons or residues are inserted and denoted by '#'. If a suitable alignment counterpart from the database is not found for the target sequence, the user can contact us.

FTP. Various formats of the database are available for download from NCBI's repository under the directory 'kabat'. Currently active formats include a FASTA-like raw sequence format and the database's fixed length format of 80 or fewer

characters per line and vertical alignment. Four main variations on the fixed length format exist to properly visually display single translations, pseudogene translations, J-minigenes and D-minigenes. Other immunological databases have adopted similar formats as exemplified by the three letter code amino acid translation followed by single letter code. A 'dump' version of the database is periodically updated which contains unlimited line length records more suitable for mass processing on unix-based systems.

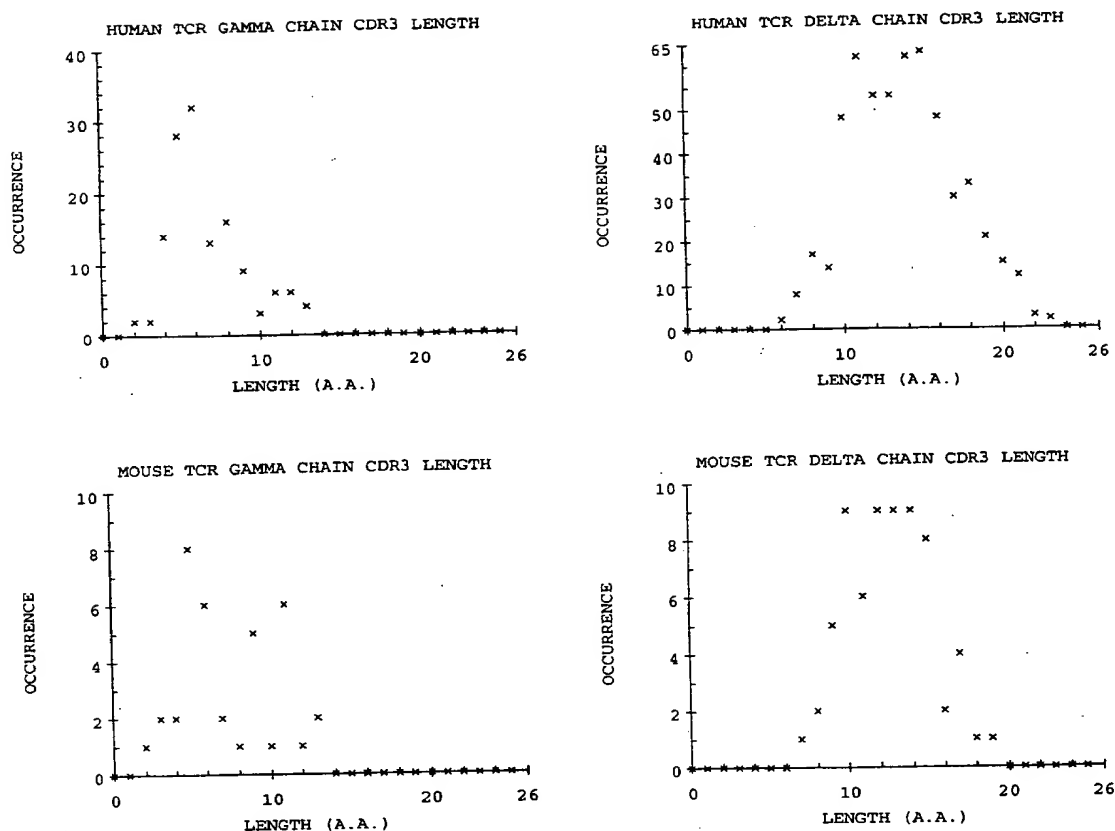

Figure 2. Length distributions of CDR3s of human and mouse TCR gamma and delta chains, based on 135 human gamma, 546 human delta, 37 mouse gamma and 66 mouse delta complete CDR3 sequences.

OTHER APPLICATIONS

As mentioned before, the Kabat Database was initially constructed for the purpose of identifying the antibody combining site (1). Starting from aligned amino acid sequences and using variability calculations, we have identified CDRs of antibody light and heavy chains, as well as those of TCRs. Such calculations can also provide useful predictions for MHC class I and II sequences (8), and to other aligned proteins sequences, e.g. HIV gp120, gp41, etc.

The importance of CDRH3 to confer fine specificity to antibodies was realized a few years ago (10). Furthermore, the unique CDRH3 nucleotide sequences have recently been used as a sensitive diagnostic test to detect residue B cell malignancies in cancer patients. Thus, many of these sequences have been determined. But most of them have been excluded from GenBank due to their relative short lengths. We have been meticulously collecting them, and realized the importance of their length distributions in antibodies of various specificities (11), and possible differences between CDRH3s of human and mouse (12). In the case of rabbit, the CDRH3s have less length variation than human and mouse. This may be compensated by the length variations of the CDRL3s (13).

The length variations of TCR alpha and beta chain CDR3s are very restricted (14). On the other hand, TCR gamma and delta chain CDR3s have more length variation, close to those of antibody heavy chains (Fig. 2). Whether they bind antigens directly is unclear.

During recent years, various research groups have decided to sequence the entire coding region of different antibody and TCR V-genes, in order to have an idea of their total numbers. On the other hand, we have discovered that pair-wise comparisons of V-gene nucleotide sequences in the Kabat Database provide very accurate estimations of their total numbers (15,16). In addition, such comparisons seem to suggest that antibody and TCR V-genes have evolved under different selective pressures (17). In the case of MHC class I sequences, comparison of their aligned sequences has elucidated a new mechanism of generating novel MHC class I molecules by random assortment of their $\alpha 1$ and $\alpha 2$ gene segments (18).

DISCUSSION

The Kabat Database has been around for 30 years. It has provided the immunology community a useful service, since it

not only is a sequence database but also incorporates vital aspects of the biology of the immune system. Various analytical methods have been developed to study the structure and function relations of proteins of immunological interest.
